Explanation	**Real-World Example**
end, backend aur database alag-alag manage hote hain.	Hospital website, API aur SQL database separate hain.
uirement ke according application servers add kar sakte hain.	Traffic badhne par additional backend servers add karna.
abase ko private network mein rakh sakte hain aur access restrict kar sakte hain.	Database sirf authorized backend server se accessible hai.
ier ko independently update aur maintain kar sakte hain.	Frontend UI update karna bina database change kiye.
ple servers aur load balancer se availability improve kar sakte hain.	Ek application server fail hone par traffic doosre server par route karna.
ntend aur backend ke deployments ko separately manage kar sakte hain.	Backend API ka naya version deploy karna.
ues ko frontend, backend aur database tiers mein isolate kar sakte hain.	Patient records load nahi ho rahe toh API aur database logs check karna.
CI/CD pipelines aur Infrastructure as Code se deployment automate kar sakte hain.	Azure DevOps pipeline aur Terraform ka use karna.
aching, load balancing aur tier-wise optimization implement kar sakte hain.	Frequently accessed data ko cache karna.
rent teams apne respective tiers par kaam kar sakti hain.	Frontend, backend aur database teams independently kaam karti hain.

Interview mein yaad rakhna, bha
Independent Deployment. Hig

ai: 3-Tier Architecture ke major benefits hain Scalability, Security, Maintainability, High Availability aur
gh availability aur performance automatically nahi milte; unke liye proper configuration zaroori hai.
